

Hepatitis C Transmission Risk Saskatoon Health Region, 2016

Highlights

- Among individuals with hepatitis C infection in 2016, 70.6% (106/150) reported a history of injection drug use. Just under 30% did not report injection drug use as a risk factor.
- In 2016, the second most frequently reported transmission risk was other non-injection drugs, and the third was time spent in prison. See [About the Data](#) for definitions.
- Among those who did *not* report injection drug use as a transmission risk, the most frequently reported risks were tattoo (33%), drug use – illicit (non-injection) (33%) and spent time in prison (33%) (not shown).
